# CHAPTER 1

## PROJECT DESCRIPTION

### ABSTRACT

Electric Vehicles (**Ather Rizta**) are vital for reducing emissions and promoting sustainable transport. This study compares three popular tools—SIMULINK, QSS, and ADVISOR—for EV modelling and simulation. These tools help analyze key EV components like batteries, motors, and powertrains. The research evaluates their accuracy, speed, and usability, offering insights to engineers and researchers for selecting the best tool for EV design tasks.

### INTRODUCTION

Electric Vehicles (EVs) are key to reducing pollution and dependence on fossil fuels. Designing EV systems involves understanding complex interactions between batteries, motors, and control systems. Simulation tools like SIMULINK, QSS, and ADVISOR simplify this process by predicting performance and optimizing designs.

#### Toolbox Introduction:

- **SIMULINK:** A powerful tool in MATLAB for building and simulating dynamic systems. It uses a block-based design, making it great for detailed EV modelling, like motors, batteries, and control systems.
- **QSS (Quantized State Systems):** A simpler and faster way to simulate EVs by focusing on steady-state behavior rather than detailed changes over time, saving computation time.

- **ADVISOR (Advanced Vehicle Simulator):** A ready-to-use tool for analyzing EVs. It has built-in models for key components like batteries and powertrains, making it easy to quickly test and optimize designs.

## CHAPTER 2

### **REQUIRED INPUT PARAMETERS AND CALCULATIONS**

#### **Vehicle Specifications:**

For consistency across toolboxes, the following standardized vehicle specifications are used in all models:

**Vehicle Type: 2-Wheeler Electric Vehicle (Ather Rizta)**

**Kerb Weight: 119**

**Pay Load: 80**

**Total Weight:199**

**Battery Pack: 2.9 kWh**

**Battery Voltage: 5V**

**Battery Capacity: 60Ah**

**Frontal Area: 0.855 m<sup>2</sup>**

**Tyres: 90/90 R12**

**Coefficient of Rolling Resistance: 0.02**

**Drag Coefficient: 1.5**

**Motor Type: Permanent Magnet Synchronous Motor (PMSM)**

**Motor Power (continuous): 4.3 kW**

## Selected Drive Cycle: NEDC (New European Driving Cycle)

## Throttle Parameters:

 **Block Parameters: Longitudinal Driver** ✕

Longitudinal Driver (mask) (link)

A parametric longitudinal speed tracking controller for generating normalized acceleration and braking commands based on reference and feedback velocities.  
Use the external actions to input signals that can disable, hold, or override the closed-loop commands determined by the block. The block uses this priority for the input commands: disable, hold, override.

## Motor Controller System:

## Controlled PWM Voltage:

Simulink provides an inbuilt Controlled PWM Voltage block. This block is used for providing the proper pulse inputs to the H-Bridge circuit.

This block creates a Pulse-Width Modulated (PWM) voltage across the PWM and REF ports. The output voltage is zero when the pulse is low, and is equal to the Output voltage amplitude parameter when high. Duty cycle is set by the input value.

At time zero, the pulse is initialized as high unless the duty cycle is set to zero or the Pulse delay time is greater than zero. The Simulation mode can be set to PWM or Averaged.

In PWM mode, the output is a PWM signal. In Averaged mode, the output is constant with value equal to the averaged PWM signal.

**Block Parameters: Controlled PWM Voltage**

Activate Windows  
 Go to Settings to activate Windows.

The **PWM & REF** connections are for the corresponding ports on the H-Bridge circuit. The 2 reference inputs correspond to the throttle inputs given by the driver. The block generates corresponding pulse width as per the accelerations and brakes applied by the driver himself.

**H-bridge:** This block represents an H-bridge motor drive. The block can be driven by the Controlled PWM Voltage block in PWM or Averaged mode. In PWM mode, the motor is powered if the PWM port voltage is above the Enable threshold voltage. In Averaged mode, the PWM port voltage divided by the PWM signal amplitude parameter defines the ratio of the on-time to the PWM period. Using this ratio and assumptions about the load, the block applies an average voltage to the load that achieves the correct average load current. The Simulation mode parameter value must be the same for the Controlled PWM Voltage and H-Bridge blocks.

**Block Parameters: H-Bridge**

☒ Auto Apply

> Reverse threshold voltage	0.0001	V
> Braking threshold voltage	0.0001	V
<b>Bridge Parameters</b>		
> Output voltage amplitude	51.1	V
> Total bridge on resistance	0.1	Ohm
Freewheeling diode on resistance	0.05	Ohm
Freewheeling diode off-state conductance	1e-6	S

Connection **REF** is for the reference input. This combined with the PWM connected will form the pulse input for the H-Bridge. Here, the REF input is connected to the Electrical Reference (ground).

Connection **REV** corresponds to the reverse motion of the motor which essentially means, the backward motion of the vehicle. Here, the backward motion of the vehicle is not accounted for and so, the port is connected to the electrical reference.

Connection **BRK** is for the braking of the vehicle. Since, the PWM mode results in a huge amount of simulation time, Averaged mode is selected for this simulation. Load current characteristics are considered to be smoothed here.

Also, the **Regenerative Braking** is an abled for the simulation. This means, when the vehicle starts decelerating, corresponding amount of charge will be fed back to the battery.

Accordingly, the **BRK** input is connected to a Controlled Voltage Source. This will generate emf corresponding to the intensity of brakes applied and fed the power back to the battery.

The Output Voltage Amplitude of the H-Bridge circuit is given the same value as the rated DC supply voltage of the DC motor.

## Motor System:

### DC Motor:

This block represents the electrical and torque characteristics of a DC motor. The block assumes that no electromagnetic energy is lost, and hence the back-emf and torque constants have the same numerical value when in SI units. Motor parameters can either be specified directly, or derived from no-load speed and stall torque. If no information is available on armature inductance, this parameter can be set to some small non-zero value. When a positive current flow from the electrical + to - ports, a positive torque acts from the mechanical **C to R ports**. Motor torque direction can be changed by altering the sign of the back-emf or torque constants.

Simulink provides an inbuilt model block for DC motor which converts electrical input into mechanical rotational output.

**Note:** Here, the blue color corresponds to the electrical side of the motor and the green color corresponds to the mechanical side. Here, the motor field type is kept as Permanent magnet and the model parameterization is done by rated load and speed. The armature inductance and the mechanical parameters are given their default values.

The **connection R** represents the Rotor (rotational output) while the connection **C** is for the Casing (stationary). Thus, the R port is connected to the input of the vehicle subsystem created earlier. The C port is connected to a **mechanical rotational reference**.

The + and - terminals of the motor are connected to the motor controller. If these terminals are directly connected to a battery, the required DC motor will run on the rated capacity of the battery. This will eventually result into no control over the DC motor and the vehicle will run at top speed throughout the simulation. Thus, a motor controller is very much needed.

### Simple Gear:

The input for this subsystem is taken as the Rotational speed of the motor. This input is fed to the front axle through a Simple Gear representing the **Final Drive Ratio of 7.8**. Here, the rotational direction of the output shaft is kept the same as that of the input shaft. Also, no meshing losses are considered for the simulation.

## Vehicle System:

The **Vehicle Body** block basically represents a two-axle vehicle body in longitudinal motion.

The block accounts for body mass, aerodynamic drag, road incline, weight distribution between axles due to acceleration road profile.

Here, the connection **H** is the mechanical translational conserving port hub. **NF & NR** correspond to the output ports for normal reaction forces on front axle and rear axle wheels respectively. Connection **V** represents the actual output translational velocity of the vehicle. **beta** is the road inclination angle & **W** corresponds to the headwind speed (headwind - direction opposite to that of vehicle). The gross weight is given to be **199 kg**.

### Battery System:

To ensure the battery supplies current as per the requirements of the motor controller and not the rated current, a **Current Sensor & Controlled Current Source** pair is connected.

Connections + and - are conserving electrical ports through which the sensor is inserted into the circuit. Connection I is a physical signal port that outputs current value.

**Block Parameters: Battery**

Battery (mask) (link)

Implements a generic battery model for most popular battery types. Temperature and aging (due to cycling) effects can be specified for Lithium-Ion battery type.

## Power GUI block:

The block should be named 'powergui' and should be located at the highest level of your diagram where Sims cape Electrical Specialized Power Systems blocks are found.

## Simulation:

The system is running for simulation for **1180 s** which is the total time for which the input drive cycle is defined.

A **Solver Configuration** is added to ensure proper solving of the mathematical equations by the model.

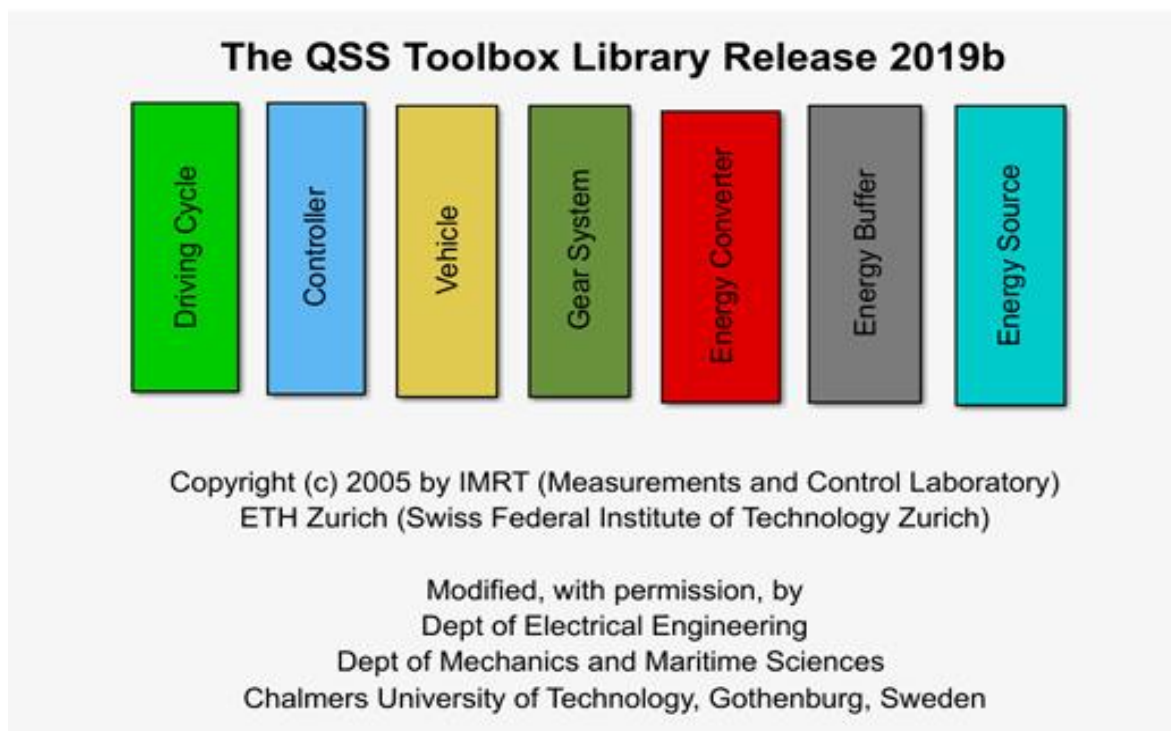

**Scopes** are connected to analyze different outputs such as the SOC of the battery, the reference velocity & the actual velocity of the vehicle and the distance covered by the vehicle during the total run.

The 2 velocities are first converted from **m/s to kmph** values. For this, simple Gain blocks are used. The distance is calculated by simply time-integration of the vehicle velocity.

## **EV Modeling Using QSS TOOLBOX**

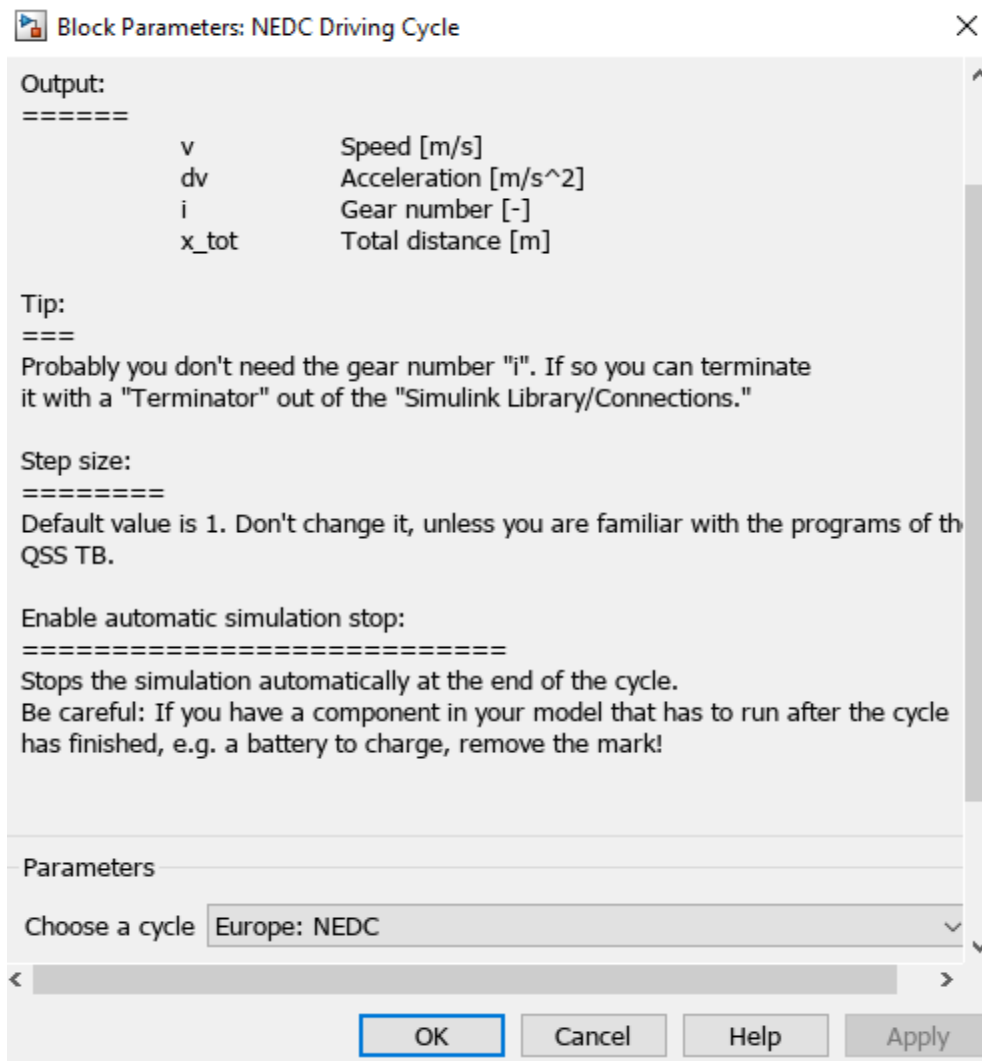

The QSS Toolbox (Quantized State Systems Toolbox) in MATLAB is a tool for simulating systems in a smarter, event-driven way. Instead of continuously calculating every little change, it only updates when something significant happens, like a key state crossing a set threshold. This makes it perfect for electric vehicles (EVs), where you often deal with sudden changes—like switching between regenerative braking and acceleration or managing quick shifts in power.

By focusing on important events, the QSS Toolbox keeps simulations efficient, saving time and resources, while still accurately capturing critical behaviors. It's a great fit for dynamic systems where precision matters but you don't want the heavy computational load of traditional methods.

## Drive Cycle Block:

Here is insertion of drive cycle and specified it as NEDC driving cycle.

### Vehicle Block:

Here is insertion of Vehicle Block and specified it as per mentioned table.

Block Parameters: Vehicle X

## EV MODELING IN MATLAB USING QSS TOOLBOX:

## EV Modeling Using ADVISOR TOOLBOX

The ADVISOR (Advanced Vehicle Simulator) Toolbox is a tool built for MATLAB and Simulink that helps engineers quickly design and analyze different types of vehicles, such as electric cars, hybrids, and traditional gas-powered vehicles. It comes with ready-made templates and components, so users don't have to create models from the ground up. This makes it easier to test and improve vehicle performance efficiently.

Only the vehicle's dimensional and mechanical performance parametric values and drive cycle of NEDC are given as an input, rest all the electrical parameters are kept constant.
